with the understanding that $\hat{f}(0) = 2$ and $\hat{g}(0) = 1$.3. The following exercise illustrates the principle that the decay of \hat{f} is related to the continuity properties of f .(a) Suppose that f is a function of moderate decrease on \mathbb{R} whose Fourier transform \hat{f} is continuous and satisfies

$$\hat{f}(\xi) = O\left(\frac{1}{|\xi|^{1+\alpha}}\right) \quad \text{as } |\xi| \rightarrow \infty$$

for some $0 < \alpha < 1$. Prove that f satisfies a Hölder condition of order α , that is, that

$$|f(x+h) - f(x)| \leq M|h|^\alpha \quad \text{for some } M > 0 \text{ and all } x, h \in \mathbb{R}.$$

(b) Let f be a continuous function on \mathbb{R} which vanishes for $|x| \geq 1$, with $f(0) = 0$, and which is equal to $1/\log(1/|x|)$ for all x in a neighborhood of the origin. Prove that f is not of moderate decrease. In fact, there is no $\epsilon > 0$ so that $\hat{f}(\xi) = O(1/|\xi|^{1+\epsilon})$ as $|\xi| \rightarrow \infty$.[Hint: For part (a), use the Fourier inversion formula to express $f(x+h) - f(x)$ as an integral involving \hat{f} , and estimate this integral separately for ξ in the two ranges $|\xi| \leq 1/|h|$ and $|\xi| \geq 1/|h|$.]4. Bump functions. Examples of compactly supported functions in $S(\mathbb{R})$ are very handy in many applications in analysis. Some examples are:(a) Suppose $a < b$, and f is the function such that $f(x) = 0$ if $x \leq a$ or $x \geq b$ and

$$f(x) = e^{-1/(x-a)} e^{-1/(b-x)} \quad \text{if } a < x < b.$$

Show that f is indefinitely differentiable on \mathbb{R} .(b) Prove that there exists an indefinitely differentiable function F on \mathbb{R} such that $F(x) = 0$ if $x \leq a$, $F(x) = 1$ if $x \geq b$, and F is strictly increasing on $[a, b]$.(c) Let $\delta > 0$ be so small that $a + \delta < b - \delta$. Show that there exists an indefinitely differentiable function g such that g is 0 if $x \leq a$ or $x \geq b$, g is 1 on $[a + \delta, b - \delta]$, and g is strictly monotonic on $[a, a + \delta]$ and $[b - \delta, b]$.[Hint: For (b) consider $F(x) = c \int_{-\infty}^x f(t) dt$ where c is an appropriate constant.]5. Suppose f is continuous and of moderate decrease.(a) Prove that \hat{f} is continuous and $\hat{f}(\xi) \rightarrow 0$ as $|\xi| \rightarrow \infty$.Exercise 5. Show that if $\hat{f}(\xi) = 0$ for all ξ , then f is identically 0.(b) Show that if $\hat{f}(\xi) = \frac{1}{2} \int_{-\infty}^{\infty} [f(x) - f(x-1/(2\xi))] e^{-2\pi i x \xi} dx$.[Hint: For part (a), show that $\hat{f}(\xi) = \frac{1}{2} \int_{-\infty}^{\infty} [f(x) - f(x-1/(2\xi))] e^{-2\pi i x \xi} dx = \int \hat{f}(y) g(y) dy$ for part (b), verify that the multiplication formula $\int f(x) \hat{g}(x) dx = \int \hat{f}(y) g(y) dy$ still holds whenever $g \in S(\mathbb{R})$.][Hint: (b) verify that the multiplication formula $\int f(x) \hat{g}(x) dx = \int \hat{f}(y) g(y) dy$ still holds whenever $g \in S(\mathbb{R})$.]The function $e^{-\pi x^2}$ is its own Fourier transform. Generate other functions for part (b) by multiplying $e^{-\pi x^2}$ by other functions in $S(\mathbb{R})$. What must \hat{f} be for f to be a constant multiple of $e^{-\pi x^2}$? To decide this, prove that $\mathcal{F}^4 = I$. Here $\mathcal{F}(f) = \hat{f}$ and $\mathcal{F}^2(f) = f$. (see also Problem 7).The Fourier transform, $\mathcal{F}_4 = \mathcal{F} \circ \mathcal{F} \circ \mathcal{F} \circ \mathcal{F}$, and I is the identity operator on $S(\mathbb{R})$. (see also Problem 7).

7. Prove that the convolution of two functions of moderate decrease is a function of moderate decrease.

$$\int_{\mathbb{R}} f(x-y) g(y) dy = \int_{|y| \leq |x|/2} + \int_{|y| \geq |x|/2}$$

[Hint: Write $\int_{\mathbb{R}} f(x-y) g(y) dy = \int_{|y| \leq |x|/2} + \int_{|y| \geq |x|/2}$ while in the second integralin the first integral $f(x-y) = O(1/(1+x^2))$ while in the second integral $g(y) = O(1/(1+y^2))$.]8. Prove that f is continuous, of moderate decrease, and $\int_{-\infty}^{\infty} f(y) e^{-y^2} e^{2\pi i x y} dy = 0$ for all $x \in \mathbb{R}$, then $f = 0$.[Hint: Consider $f * e^{-x^2}$.]9. If f is of moderate decrease, then

$$(14) \quad \int_{-R}^R \left(1 - \frac{|\xi|}{R}\right) \hat{f}(\xi) e^{2\pi i x \xi} d\xi = (f * \mathcal{F}_R)(x),$$

where the Fejér kernel on the real line is defined by

$$\mathcal{F}_R(t) = \begin{cases} R \left(\frac{\sin \pi t R}{\pi t R} \right)^2 & \text{if } t \neq 0, \\ R & \text{if } t = 0. \end{cases}$$

Show that $\{\mathcal{F}_R\}$ is a family of good kernels as $R \rightarrow \infty$, and therefore (14) tends uniformly to $f(x)$ as $R \rightarrow \infty$. This is the analogue of Fejér's theorem for Fourier series in the context of the Fourier transform.

10. Below is an outline of a different proof of the Weierstrass approximation theorem.
